One of the more intriguing forms of symbolism in Bali is based upon a somewhat uncommon use of nature. In certain agricultural ceremonies, various species of widely-found plant, otherwise ostensibly unimportant, are accorded a temporary ritual prominence. This is largely, it seems, because their normal designations refer in some way to the conditions of ideal cultivation, in particular to the phases of growth and the harvest yields, of irrigated rice. In each instance, there is a terminological association which relies on the systematic employment of homonymy or assonance, in a broad sense. While this does not preclude the possibility of other types of link so far untraced, it suggests the relevance of language and sensory resemblances, in the formation of symbolic connexions, in a manner which may previously have been overlooked.

An examination of the theme and stated purpose of these cyclical rituals – the re-enactment and encouragement of successful agriculture – poses broader questions about their sociological function. Although the concerns are not unfamiliar, some of the more obvious approaches seem to fall short of providing an appropriate answer. This is so, for example, for arguments in terms such as the re-affirmation of social solidarity; as mystical alternatives in the face of technological inadequacy (Beattie 1964: 207); as a method of mnemonics and ordering experience (Douglas 1966: 58-72; 1968: 369); and, additionally, as a regulating mechanism for cultivation (Geertz 1967: 233; 1972a: 30-32; cf. 1966a: 6-9; 28-9; 1966b: 52). For, most agricultural ceremonies are performed by individual farmers alone on their rice fields; capital investment in technical installations offers a potential means of substantially reducing risks and uncertainty; while the frequent disjuncture between the timing of offerings and the developmental stages of rice, with its concomitant work schedules, points to the weaknesses of hypotheses based on either the naive instrumentality or the organisational character of these rites. Under such circumstances, an interesting interpretation is suggested by the contrast of cultural statements of belief with an analysis of economic relationships in practice. On the one hand, religion emphasises the attribution of final responsibility for the fertility of the crop to supernatural agencies; on the other, ethnographic evidence indicates that insufficiency stems in no small part from the problems in social cooperation and in the democratic constitution of irrigation associations. For their structure tends to lead to the dominance of small-scale farmers, to a relatively low level of investment and possible conflicts of interest which are denied public expression. Agricultural ceremonies may, therefore, embody an alternative explanation
for the deficiencies of, and stresses within, the basic productive
groups, and so may indirectly help to maintain them and the accom-
panying ideal of the strict equality of members of a corporation.

The organisation of irrigated agriculture in certain parts
of Bali has been described in some detail.3 In most features,
the region round the settlement of Tengahpadang in Central Gian-
yar, from which the information used here is drawn, corresponds
with existing accounts. Rice forms the main subsistence product
and is obtained through an intensive system of annual double-
topping of a number of varieties, most of which take some five
months from seed to harvest, and just under six to complete a
cycle (cf. Adatrechtbundels XV: 50). Irrigation is controlled by a
special group, the subak, composed of persons whose terraces
are fed from a single source. In this case, most riceland owned
by the villagers lies on a long sloping ridge supplied by a local
association known as Subak Langkih. From a river dam about five
miles upstream, the water is led a tortuous route between ravines,
through an intricate system of aqueducts, canals and dividing-
blocks of different sizes, eventually to individual plots. The
irrigation works are technically ingenious, but rely far more on
the extensive use of labour to maintain the simple conduits,
generally of earth or mud and stones, than on capital for secure,
nowadays concrete, structures (Liefirnck 1969: 47-57). As a
result, patching breaches is an almost incessant activity, espe-
cially in the rainy season (nor is this an isolated instance, see

This whole system is under the management of the subak,
which allocates water, collects its own agreed taxes and superv-
ises much of the day-to-day administration. Owing to its size
and topography, Subak Langkih is divided into five territorially
discrete, but adjacent, sections, or tempak, each with its own
sub-channel, council and officials, under an overall head, the
klian pekasik. It is from these that the peasant farmers ac-
quire water in units of tenak, a proportion of the total flow,
adequate here to irrigate on average roughly a third of a hectare
(Geertz 1967: 230-31; but cf. Adatrechtbundels XV: 44; in
Tengahpadang this is commonly known as (bi)bit tenak, see Ada-
atrechtbundels XV: 37). Unlike the settlement wards, or banjar,
persistent factionalism does not seem to be a salient feature of
subak in this area. The main informal cleavage is between
the restricted number of large cultivators and the majority with
one bit tenak or less, including some share-croppers who under-
take the obligations of members as part of their settlement.4
While the association assesses its own levies according to the
quantity of water obtained, labour and voting rights are per
capita, not dependent on the size of holdings. Thus, 'subsis-
tence farmers' comprise most of the membership, preponderate
at the meetings where collective decisions are reached and influence
the direction of public policy.

The timing of agriculture generally is regulated through
the head of the subak in conjunction with its temple priest, or
penangku, and may form part of a regional arrangement for stag-
gering the distribution of water supplies (Adatrechtbundels XV:
51-2; Geertz 1972a: 30-31; cf. Liefirnck 1969: 62-3). For
ritual, this is complicated by the existence of two separate
calendars in Tengahpadang and elsewhere (see Goris 1960a: 118;
Grader 1960: 276-8) which are of some importance in the follow-
ing discussion. The first is the Hindu system (Goris 1960a:
115-6) of twelve solar-lunar months, in which the principal
dates of religious significance are the full moon, purmama,
and the new moon, etlem. The second is the so-called Javanese-
Balinese, or uku, calendar, based on the numerical computation
of a set of concurrent weeks, ranging in length from one to ten
days, in which the combination of the three most important weeks,
of five, six and seven days, defines a fixed 210-day cycle.
The uku system in particular is completely divorced, therefore,
from the flow of observable natural events and seems to form a
separate taxonomic and conceptual framework (Geertz 1966b: 42-
53), in which the permutations emphasise its distinct, abstract
mathematical order.5 Apart from their mundane application,
these two schemes between them establish the dates for scheduled
religious holidays and temple festivals, and indicate auspicious
or dangerous periods for a wide variety of activities. In
Subak Langkih, both calendrical systems intersect in the or-gani-
sation of the rice-cycle rites.6 So, for example, the main
temple festival, (p)odalan agung occurs on Purnama Kedasa, or
every full moon of the tenth solar-lunar month, whereas the
regular offerings in the ricefields normally fall on every fif-
teenth day, or kajeng-mang, by the overlap of kajeng, the third
day of the three-day week, with umanis, the first day of the
five-day week. Although Geertz has argued that the ceremonies
are synchronised with the stages of cultivation (see below), in
Tengahpadang at least, there is no simple correspondence, for
the rites follow a largely predetermined pattern.

There is another complexity. The agricultural seasons alternate in this area between a rigorously supervised cycle,
referred to as kertamasa, in which all work and ritual are co-
ordinated in theory through the head of the association on pain
of punishment, and an open one, gegadon (Liefirnck 1927: 153;
Wirz 1927: 249), when each farmer is notionally free to decide
his own schedule. In effect, the difference is not always so
great, as the peasants fear increased damage from migrating
pests if the harvesting is serial. One concomitant of this
seasonal oscillation is that certain major ceremonies are per-
formed by the subak, during which members are placed under
the obligations of the temple priest, or penangku, by the overlap of
kajeng-mang, the third day of the three-day week, with umanis, the
first day of the five-day week. Although Geertz has argued that the ceremonies
are synchronised with the stages of cultivation (see below), in
Tengahpadang at least, there is no simple correspondence, for
the rites follow a largely predetermined pattern.

The timing of agriculture generally is regulated through
the head of the subak in conjunction with its temple priest, or
penangku, and may form part of a regional arrangement for stag-
gering the distribution of water supplies (Adatrechtbundels XV:
51-2; Geertz 1972a: 30-31; cf. Liefirnck 1969: 62-3). For
ritual, this is complicated by the existence of two separate
calendars in Tengahpadang and elsewhere (see Goris 1960a: 118;
Grader 1960: 276-8) which are of some importance in the follow-
ing discussion. The first is the Hindu system (Goris 1960a:

Tengahpadang at least, there is no simple correspondence, for
the rites follow a largely predetermined pattern.
An attempt to analyse the entire series of ceremonies, offerings and prayers would prove a daunting, if not impossible, task and is beyond the scope of the present work. One small part of this complex, however, does contain a relatively discrete set of ritual elements, which are of some theoretical interest, for their novelty if nothing else, as they appear to be based on the recognition of different forms of sound association, in particular homonymy and assonance, and the possible applications of these in a more or less ordered fashion in symbolisation. Nor is the use of such types of correspondence restricted to agricultural rites alone. A similar development of language forms is evident in other contexts, for example in verse and proverbs, in the traditional 'romantic operettas', arja (McPhee 1966: 7; cf. 294-303), or even the humble, but inveterate, Balinese habit of punning.

The verse form of the quatrains, known among the Malays as the pantun, is also found in Bali (sometimes under the name of sesenggakan; cf. van der Tuuk 1897). This consists of two couplets, arranged so that ideally there is systematic assonance between the first and third lines, and also the second and fourth. The opening couplet may provide an allusive reference to a theme taken up more directly in its successor, or they may be effectively unrelated (for a more detailed discussion, see Wilkinson & Winstedt 1957). Commonly the first two lines alone are spoken in Bali, the audience either knowing or being left to infer the remainder through assonance.

Significantly perhaps, quatrains may be found in a religious setting. For instance, the temple of Duur Bingin in Tengahpadang possesses a pair of deities, the Barong Lanaung, who are manifest as gigantic puppets in the guise of a black male and a white female (Govarrubias 1937: 287 & 355-6). This couple has, it is believed, the power to confer fertility on childless marriages and are recognised throughout much of the island. In the month following the religious holiday of Galungan (according to the Javanese-Balinese calendar; Goris 1960a: 124-5), they are carried around the villages and animated from inside by trained members of a voluntary association, accompanied by an orchestra. A speciality of this pair is the paid performance of songs, not infrequently with explicitly sexual overtones! In the example which follows, the structure can be seen clearly, although there is no particular link between the couplets. Here, the initial two lines are essentially nonsense phrases which provide the pattern for the closing section. A rough translation follows:

Sok pecok pedemin cicing,
Memula lateng di Bangkiaangsidem,
Nyaka bocok, nyaka tusing,
Lamun suba anteng ajak medem.

A dented basket slept on by a dog,
Planting nettles in Bangkiaungsidem (a village in East Bali),
I like her whether she is ugly or not,
Provided that she is prepared to sleep with me.

A similar, if simpler, form is found in some proverbs, sesongaan, such as:

Celablingkah di batan biyu,
Gumi linggah ajak liyu.

Broken potsherds (or tiles) beneath a banana tree,
The world is big (broad) with much (in it).

Deliberate plays on homophones, or homonyms, in punning is found in village conversation and exchanges, particularly in public on the roads and in coffee-stalls. A simple illustration from one of the most adept perpetrators in Tengahpadang should suffice. The standard form of greeting in Bali is to ask the other person where they are going, which elicits a reply varying with the amount of information it is wished to convey. In ordinary Balinese this is 'bakal kija?' (literally: where will you (go to)?), normally shortened to 'ka(l) kija?', with the terminal -l, elided. On being addressed once, the punster chose to mis-interpret this as 'kaki ja?', or 'where is your grandfather?'. So he riposted accordingly with 'di sawa!', 'in the graveyard!' - to hoots of laughter from bystanders. On another occasion, with a political undercurrent, he shamed publicly an unpopular local official,8 notorious for muddling Balinese and Indonesian (the national language), by treating the same question as a linguistic hybrid. Here, 'ka(l) kija?' was construed as the Indonesian kaki (Foot) and low Balinese ja (where), or 'where are your feet?'. The man was promptly put down with the response: 'di atas tanah', 'on the ground', in an equal confusion of languages. These retorts were duly circulated around the village with evident approbation.

In a more serious vein, sound association occurs in certain rituals. The most elaborated use is found in manten padî, the main ceremony after the completion of the harvest, when the padi has already been stored in the granary, with offerings, banten, to the goddess of rice, Dewi Sri, in effigy in a decorated bundle of rice placed by the eastern wall (for a synopsis of the rice-cycle rites, see Table 2, and for the significance of the directions: 'The Path of the Soul', in this volume). A different form is found in two earlier rituals: musi, planting the diwasca (for the linked meanings, see van der Tuuk 1897), sacred clumps of padi used later to make the figure of the deity; and a small rite commonly held at the end of mebiyu kukang, which is considered to effect the 'marriage' of the rice, and sometimes ward off pests as well. Finally, identical plants are included in the marriage ceremony, mesakapan, with a similar interpretation.
Mantrenin padi is performed some time after the harvest and drying of the grain (in Bali, this is with the ears still on the stalks, which requires early reaping). In theory, no rice can be sold beforehand (Grader 1960: 277-8), although it is not unusual, in fact, for poor families to ignore this injunction out of economic necessity, for the rite may take place months later, each household acting independently. Offerings of a relatively elaborate character are placed in the granary, and at ritual sites throughout the compound, particularly in the ancestor shrines. Some of the names are interesting, for example lumbung bek, meaning simply: full granary. These compose part of a formidably complex and locally variable system which, as Hooykaas has pointed out, remains largely unstudied (C. Hooykaas 1973a: 169; for an introduction see: Belo 1953; J. Hooykaas 1961).

My concern here is instead with some of the ritual appurtenances in the form of a set of plants which are placed at a remove from the principal offerings, on the outside walls of the granary. The classification of botanical species in Bali has been little examined, although some of these are listed and their medicinal properties designated in the palm-leaf manuscript, the Taru Pramana which states how a culture hero Mpu Kuturan distinguished them. Other woods are differentiated according to their purity, and hence suitability for ritual use. Many of the common names provided in the Taru Pramana are related to ordinary Balinese words in some form. For instance, the manuscript includes: buyung-buyung putih (lit: white flies), or uyah-uyah (uyah = salt). In certain cases, there is an apparent reference to morphological or physiological features of the species, so that tebel-tebel (tebel = thick) has both thick leaves and spreads fast (Van der Tuuk 1897). For others, informants were aware of no explanation. For present purposes, it is adequate to note these unexamined aspects of classification.

The species chosen for use in mantrenin padi vary somewhat across the island (cf. Wirz 1927: 316-7). In Tengahpadang, twelve plants seem to comprise the available pool, from which those actually incorporated may be drawn. All were found growing either in the house compounds, lanes or dry fields; but it is to be noted that many were not to be found in the vicinity of river-banks and none were distinguished for thriving in, or near, ricefields. It is possible that this may serve symbolically to underline the conceptual separation of the growing padi on the terraces from the dry product stored in the compound for consumption.

The question arises as to why these twelve species in particular should be selected from all those known to adorn the sides of the granary. To the best of my knowledge, they are not used on any other ritual occasion. Wirz (1927) has suggested that one reason may be their bitter taste or poisonous effects, which are believed to deter evil spirits and demonic influences, although he admits that this cannot furnish a complete explanation. However, in his version the plants are hung around the doorway as a barrier, not on the sides as in Tengahpadang. This view also does not account for the many species which are neither toxic nor considered potent against malevolent supernatural beings. Further, one of these, kayu sugih, is in fact an ingredient of porridge and a dye-stuff as well; while tebel-tebel is a compound in ear medicine. Apart from this, they are apparently of little nutritional or practical value. So there are no obvious clues as to any systematic grounds for their inclusion to be gleaned from a study of their use, habitat or qualities, which I could discover. Some might be included if a diverse, and unsatisfactory, set of characteristics were made: as an example, inih-inih is assumed to be propitious if it grows in the ancestral shrine area, but this merely compounds the difficulties.

There is, however, one important way in which all these plants form a single class. This is their terminological value for sound association. When I first documented the ceremony, this was indicated to me with pride by some villagers. For, in contrast to much religious knowledge, held to be the preserve of the high caste priests, Pedanda, and about which the peasants generally professed ignorance, they stated that they were aware of the significance of the leaves. In native exegesis, these are seen mainly as homonyms or assonants of terms referring to the attributes of proper, or ideal, agricultural production which it is intended to induce. It is worth examining the series in some detail to show just how perspicacious this commentary is.

As the investigation of a number of different performances of the rite showed no discernible pattern in the order in which the plants were arranged, I shall take them as they occurred in the most inclusive instance. Tebel-tebel may be related to tebel, thick (repetition in Balinese indicates, among other things, plurality or emphasis). Tegteg has a range of meanings, including fixed or substantial; while paku kenyeng can be linked with paku, fern, and kenyeng, to smile or laugh. Inih-inih is of interest, as inih signifies: not quickly finished, used sparingly (Van Eck 1876). Nasi-nasi, in a similar fashion, can be treated among its other meanings as a possible reduplication of nasi, cooked rice, hence food. There follow three plants: kayu padi, kayu emas and kayu sugih; kayu is the ordinary Balinese word for wood, padi is the English paddy, emas is commonly translated by gold (both the metal and the colour), while sugih means wealthy or rich. Next is the curious sengeng oatu, for sengeng generally stands for a stopper and oatu is a measure for rice (with a hole in the bottom).

The remaining terms are more complex. Sri benben seems here to refer to Sri, the goddess of rice, but also a word which

</table>
may be used to indicate padi; while *benben* can be a wasp. Of significance, though, the latter is held to be an assonant of *emben*, leafy or voluminous. Similarly *dingding akh* appears to be literally: *dingding*, a woven coconut-leaf trellis and *akh*, day- or sun-light. With a slight shift of the vowel-sounds, however, one obtains *dingdong*, to dry in the sun. (This has been noted out to be "*mebanten tipat balang"* in *der Tuk* (1897) and is also the villagers' interpretation.) It may be worth recording that *ding* and *dong* are the terms for two notes in the Balinese pentatonic scale, the others being suitably: *dong*, *dung* and *dang* (McPhee 1966: 58-61). Of these plants, those which are given in the Taru Pramana tend to be identified there as cool, *etis*, a quality applied *inter alia* to a household to indicate the absence of acrimony and an adequate supply of food, with a granary which diminishes slowly (popular opinion maintained that the second of these characteristics was the determinant of the first!).

The final, and apparently least used plant is *pati(h)*, the main one to present problems, not least as the Balinese were uncertain whether it should be read as *pati* or *patih*. The latter is commonly applied to a traditional royal court official, but the former has a vast range of referents (see van der Tuuk 1897). *Kalah* may be translated as defeated or lost. In contrast, others thought that the word should be *kala*, a class of demonic spirit. At least one family did not include this species, as they were undecided as to its meaning and said that they feared the consequences were it to turn out to be 'defeated minister'. An ingenious, if unsubstantiated and somewhat ungrammatical, argument was put forward by some of the more pensive, who surmised that it referred *pati* as the handle of a knife (of the blade used to cut padi, *onggapan*) and *kalah*, as either defeated or lost, to give: to lose the knife-handle (as the rice is so thick), or to defeat the knife (for the same reason). If nothing more, this example should at least provide some insight into the processes of reasoning in symbolism developed by villagers.

This discussion indicates that the names of the plants included in *manoset padi* may signify, among other things, the following: the fertility of the rice plants, the full maturation and subsequent drying of the crop, prolific yields and a secure supply of food which does not run out quickly, and so brings prosperity, happiness and relaxation from work. It may be recalled that some of the terms for offerings inside the granary referred to similar concerns. These themes are expatiated upon by villagers, and the more frequent associations are outlined in Table 1. Among the interesting features are the ways in which indigenous commentaries emphasize the recapitulation of the later stages of the agricultural cycle, and the material qualities desired in the harvest, with its less tangible benefits. Whereas it would be difficult to explain the selection of plants in terms of their observable characteristics, an analysis of the sound associations points to a remarkably consistent system.

A not dissimilar theme occurs in *mebanten*, but in contrast, the number of plants is much smaller and more clearly circumscribed. After the bunches of young shoots have been planted to provide the sacred rice, lengths of about a foot of the foliage of the following species are temporarily inserted in the mud together with them: *dadi* (=? *Erythrina littosperma*, a leguminous plant), *kunyit*, turmeric, *keladi*, *taro* and *andong* (unidentified, but see descriptions in de Clercq 1909: 210; Wirz 1927: 271). A shoot of *pinang*, areca-nut palm is an optional addition. Wirz (1927: 296) has suggested that it is the type of growth of this particular plants which lends itself to symbolization. For instance, *dadap* is considered to be very fast-growing and the vertical stem of the areca-nut palm may exemplify the ideal form of the ripening padi plant. On being taxed with this view, my informants readily conceded that fast-maturing, thick leaves and so forth might be involved. They argued in response, though, with a certain logic, that this applied to innumerable other species which might have served equally well. Instead, they referred me once again to the terminology, pointing out that this was not so easily substitutable. The choice was expressed in terms of a short ditty:

```
  don dadap agap etis,
  kunyit mara mekelenyit,
  keladi agap nadi,
  andong megelendong,
```

which they translated, somewhat roughly, as:

```
  dadap leaves so that (the ground) will be cool
  kunyit, it lives (or sprouts on planting),
  keladi so that it will grow,
  andong - it becomes pregnant.
```

(* *etis*, the state of ritual coolness discussed above, is highly desirable and a generally believed quality of *dadap*.)

The last three lines demonstrate the assonance between the term for the plant on the one hand, and the appropriate development of the rice on the other. *Dadap* once again stands apart, but Wirz's explanation in terms of its natural features is weak, as *dadap* is perhaps the most widely-used plant in ritual to suggest coolness in contexts where growth is hardly involved, varying from *wayang lemah*, the more or less purely religious form of the shadow-play, to *metelah-telah*, the purification of the house compound after death.

The same ingredients (kunyit, keladi and andong) are included in the rite of *mebanten* *tipat balang ring tipat kukur sidayu*, commonly tacked onto *mebityu kukung* (Table 2). In this case, they are suspended together with cakes, different types of rice and comestibles from a miniature (*dadap*) shoulder-
Tegen-tegenan, and carried three times (properly clockwise) round the ricefield containing the sacred rice. This is said to complete the 'wedding' of the padi which is now permitted to become 'pregnant', beling (see above). The same ritual shoulder-pole is borne by the male, while circumambulating the bride, during the marriage ceremony for human beings. In these last two instances, the rhyme can reasonably be construed as a reference to the fecundity appropriate to matrimony, but an interpretation of the order suggested by Wirz above would seem curiously indirect and complicated. The occasions for use of this set of plants poses a problem. On the one hand, the same triad is found at two separate stages of the rice cycle - at the moment of transplanting and then again before the emergence of the panicle and flowering. On the other, while mobanten tipat belang ring tipat kukur sidayu is generally agreed to be a necessary pre-condition for the successful fertilisation of the rice-flowers, at others it is stated that the purpose of the rite is to ward off pests at the time that the seeds are maturing! One possible resolution of this difficulty may lie in a possible difference of time-scale implied in agricultural ritual.12

This discussion has, I hope, shown that there is some evidence of the organised use of sound association in a range of social contexts, including the formation of symbols in Balinese ritual. This is not to deny the possible existence of other, or even prior, connexions. There may also be differences between the various ceremonies recorded above, and there is undoubtedly a degree of flexibility in the repertory of plants adopted in different regions, which I have not been able to study in detail. Nonetheless, associations based on verbal similarity do seem to be an important element in certain symbolic sets in Bali. This approach also has the advantage that it is able to provide a relatively simple key to the system underlying the selection.

This symbolic use of common plants is one of the most coherent and explicit aspects of the complex of rice-cycle rites. As a whole, these reiterate similar concerns to those discussed above, by invoking the assistance of supernatural beings in the re-enactment of the stages of development of the rice crop, through prayers and offerings. The form of participation and the timing of the ceremonies point, however, to the inadequacies in a number of frequently assumed, or apparently promising, interpretations of ritual. Whether or not there is synchrony between rite and rice growth may be critical to the applicability of some types of argument, but it is effectively irrelevant to a consideration of the ritual cycle in terms of providing an explanatory framework for the success or failure of agriculture, by ascribing authority to agencies of posited, but unverifiable, influence. At the same time, this offers an alternative to the public recognition of the underlying structural problems of irrigation associations. It should be stressed immediately that what is being proposed here is essentially a functional view, with its attendant limitations.

One of the rather unusual features of most of these rice-cycle rites is that, with the exception of the temple festivals, nyungsung and ngesasaka which involve both collective performances in the subak temple, the Pura Masceti, and individual ones in the fields, there is no real gathering nor corporate ritual action on the part of the association during which solidarity might be re-affirmed.13 For the ceremonies are generally carried out on the given occasion for each household separately by a member at the shrine in its own fields. They have in many ways the character of private rites, in which the collective is restricted to subordination to a set of common ritual regulations (Goody 1961: 146). The theory that these are mystical devices to deal with practical deficiencies presents problems in turn, in so far as they 'may provide a way of coping with situations of misfortune or danger with which there are no other means of dealing' in the absence of empirical knowledge (Beattie 1964: 207). On the one hand, the Balinese have developed an intricate pre-industrial technology for handling the problems of irrigation, fertilisation of the soil and so forth, even if it is not always fully utilised; on the other, there is often a discrepancy between the timing of crisis and remedy.

For many misfortunes, there are clearly laid down and immediate ritual mechanisms of avoidance or redress. This applies in the face of uncertainty or danger. So, before trucks or buses cross some of the more rickety bridges which span the innumerable gorges, offerings are not uncommonly made at the wayside. More dramatically, ten days before the National Elections in 1971, the head of the administrative village decided to organise a mass prayer in Tengahpadang to ask for the safety (saelamet) and well-being of the community. Equally, in the event of falls, illness or occasionally other mishaps, ritual responses are evoked. When a giant banyan, waringin, tree in the settlement cracked open one night during a storm, the village senior officials rapidly summoned the priests to deliberate and it was concluded that forty-two days (the product of a six- and seven-day week cycle) of public ritual was necessary to ensure the neutralisation of possible adverse consequences. Here, ceremonies are held in anticipation of danger, or in prompt reply to it.

In sharp contrast, rice-cycle ceremonies are scheduled according to calendars which define religiously auspicious periods, and so do not, in fact, necessarily fit the critical stages of agriculture. This creates certain difficulties for arguments about ritual which are based on their function of ordering attention or experience. Even Douglas' view that ritual in general
In a not entirely inapplicable argument, Gertz has remarked that a piece of ritual may be more than once briefly to the question of the functions of agricultural ceremonies as a whole in Bali. From my own experience (1964: 63), applied to agricultural rites, it appears that these are seen only as part of the overall ceremonial complex, the various stages of which are symbolically related. They are generally determined, once the first stage is achieved, by a sequence of ritual actions, the duration of which is subject to ritual control. For the practitioner, the link between the calendar of the individual shrine and the development of the rice crop is a matter of ritual timing. The calendar begins with the planting of the seed rice, and the various ceremonies which are symbolically linked to this are timed to coincide with the major stages of rice growth. Thus, the ritual schedule and the development of the rice crop are presented as a definite order in the way in which the various stages of cultivation are associated with the ritual schedule, and the main stages of padi maturation, if the tropical environment at any time in the year. The timing of the various ceremonies is therefore adjusted to fit the cycle. The system is far more elaborate than the general outline presented by Gertz (1972), but there are some months in the field, and the ceremonies to be performed must be timed according to the calendar of the rice field, as indicated in Table 1.

TABLE 1. An outline of the rice-cycle rites in Subak Langkidh

| Mubu(h)in                | Three successive rites varying in core offerings: 1) porridge with dodan leaves 2) porridge with grated coconut 3) the oau as above
|                           | To ensure that the padi grows well.                                                     | On successive dates of mubu-mubu (3 days apart) which start on the first correct combination after 12 days from mubul | May sometimes be performed after 12 days have elapsed after mubul |
Nyungsung

The main ceremony is in the subak temple and resembles a small odalan (uide in~). A smaller rite in individual fields with (ka)tipat offerings of different names, referring mainly to the desired attributes of the crop.

Outline of Main Features

Subak Priest’s Interpretation

Occurs just as the padi becomes beling, pregnant (the swelling of the rice plant). This is to ensure that the flowering will be successful.

Timing

In theory, this is varied specially to coincide with the ‘pregnancy’. It may be held on one of several propitious dates, but if possible Angarkaeih or Buda-kliwon (combinations of the 7 and 5 day weeks).

Comments

During the kertamaa cycle, this should be held to coincide with the Odalan Agung, but on the occasions observed, it was not. In practice, this is often performed on the kajeng-manis after mubui III as part of a strict 15-day series but not in phase with the padi (see text).

Odalan Agung

The full three day temple festival held in the subak temple, which requires the offices of a Brahmana priest, Pedanda to perform the rite of ngatkrang pidalan (see Belo, op.cit.)

Outline of Main Features

This happens just when the padi is about to form seeds.

Subak Priest’s Interpretation

To ask for the safety (selamet) for the maturing crop.

Timing

Held on two successive kajeng-manis dates following nyungsung.

Comments

In practice, the first may be performed with nyungsung, the latter with mebiyu kukung.

Mepinunus

Simple rites held on two successive uku dates; they include a small number of tipat.

Outline of Main Features

To ensure the safe swelling of the rice seeds. To drive away pests by giving them offerings.

Subak Priest’s Interpretation

Held according to the Hindu-Balinese calendar on Purmana Kedasa (full moon of 10th month). The odalan alit, in contrast, occurs once every 210 days, so they follow separate cycles.

Comments

Apparently both are always performed on the correct date; as the Odalan Agung follows the solar-lunar calendar, it tends in fact regularly to fall closer to pregnancy than the other rites. With nyungsung and ngesaba, these resemble standard temple ceremonies more than they do the other rice-cycle rites.

Ngokansub

A festival in the subak temple again. A small rite is held on the following day in the plot of each farmer.

Outline of Main Features

To make certain the the padi turns yellow and ripens.

Subak Priest’s Interpretation

Held 15 days later on the next kajeng-manis.

Timing

Held on the kajeng-manis after the second performance of mepinunus.

Comments

Sometimes this is far too late, when the padi is more or less ripe.

Nyehetin

Decorating the duwama, sacred rice in the form of Dewi Sri

Outline of Main Features

Perform on the kajeng-manis after ngeasaba.

Subak Priest’s Interpretation

This must often be advanced off its correct scheduled time, to enable harvesting to proceed without delay. Interestingly, this timing change is known as ngarmaling = to steal.

Timing

Performed on the kajeng-manis after ngeasaba.

Comments

Rarely carried out on the proper date as it would be far too late. Also pulled forward (ngarmaling).

Mosi

A very simple rite performed on each plot just before the harvesting begins

Outline of Main Features

Not organised by ritual calendars; fixed practically

Subak Priest’s Interpretation

Asking permission to cut Dewi Sri

Timing

Performed at the same time as Manyi.

Comments

-
When the padi is dry, the offering of cow once again in the N.E. corner of the granary, using 11 cow petik and 2 cow mumbul.

The rite performed in the granary of dressing the effigy of Dewi Sri and presenting offerings to her in front of, and in, the granary. Also offerings are laid out in each building and ritual site in the compound.

Changing the offerings in the compound and granary - to remove the ash (lit.: faeces) of the incense.

UNLESS INDICATED OTHERWISE, ALL OFFERINGS BEFORE NYANGANG ARE PLACED ON A LOW SHRINE, THE SANGAH DWAWA BESIDE THE SACRED RICE. AFTERWARDS, THEY ARE PLACED IN THE SANGAH LIMASAM, THE RAISED OFFERING TABLE, COMMONLY BUT NOT ALWAYS, BY THE POINT OF ENTRY OF WATER OR IN THE N.E. CORNER OF THE TOP FIELD.

COW ARE A SPECIAL TYPE OF OFFERING, WOVEN IN TENGEPAN FROM YOUNG COCONUT-LEAF (CF. VAN DER TUUK 1987) AND USED IN RICE-CYCLE RITUE, WITH A VARIABLE NUMBER OF 'CHILDREN' DETERMINED BY THE CALENDARIC CALENDAR.

** (KE) PAPAT, ALSO MADE FROM COCONUT-LEAF, ARE SHAPED IN MANY INSTANCES LIKE ANIMALS AND DESIGNATED ACCORDINGLY (SEE J. HOOGYKAAS 1961: 54, FOR AN ILLUSTRATION).

</table>

The end of the cycle.
of the padi, was conducted a week after harvesting had begun.
Equally seriously, in the same season, nyungsung fell on 9.3.71, sixty-six days before harvest; while the padi actually became 'pregnant' at the time of mapinunas II on 8.4.71, an entire month later. The following gegadon cycle saw the rite held still earlier, eighty days before harvest; whereas in the subsequent kertomiso it was only forty-seven days before and, for once, remotely on target. This list could be continued, but the evidence adduced should, I trust, be sufficient to show that seasonal variation and actual timing do not present as neat a picture as the ideal would imply.

It seems then that for some parts of Bali at least, analyses of agricultural ritual simply in terms of technological alternatives, mnemonic devices, or as masterplans for the cultivation system seem to fall short. While the ritual cycle was presented initially by informants as serving in part as a labour schedule, or as a marker of the phases of rice growth, further scrutiny suggests that the correspondence is poor. Such interpretations may have a certain validity at a formal or abstract level. On the ground, however, the result is less a 'model of' or 'model for', than a muddle.

The incomplete character of these arguments raises problems for which no full solution can be offered here. It does suggest, however, that it may be useful to return and re-examine the relationship between the ritual complex and the organisation of cultivation. One of the features which emerges is the striking contrast between the conception of agricultural production expressed in common belief and ritual, and the results acquired through observation. The former repeatedly emphasises the inadequacy of technology alone to produce successful crops by allocating responsibility in the last resort to supernatural beings; whereas, in practice, it seems that the variations in yield depend in no small part on the efficiency of individuals and upon the workings of the irrigation association itself. It would appear, then, that the view of cultivation propounded in ritual offers a mode of explanation (Parkin 1975: 137-9), which may be misrepresentative (Bloch 1975: 203-22).

In the first part of this paper, it was remarked that the indigenous interpretation of the sets of symbols based on sound association suggests the stages of ideal agriculture, and that the use of plants in some way helps to bring about the desired result. This is stressed in the employment of mantra, ritual formulae which invoke the various gods involved in agriculture, in particular Ibu Pretiwi, Batara Wisnu and Dewi Sri, the deities of earth, water and rice, and supplicate them to bring about the ends desired at each stage in the cycle. The forms vary greatly from farmer to farmer, depending on their knowledge of the traditional ritual language, from the local priest's recitation during nuasadèm to Dewi Sri, ending with an exhortation repeated
three times of mum(b)ui, rise (or spring) up, to the simple prayer of a peasant recorded at mebiyu kukung: 'Dewi Sri, make the rice give fruit!'

In so doing, the villagers are not denying the importance of technology in bringing about fertility, which is hardly surprising in view of their acknowledged expertise. It is said, quite simply, though, that this is a necessary, but not sufficient, condition. As they readily point out, pragmatic considerations do not always explain why one farmer has a better yield than another, nor why rain flattens one man's crops, but not his neighbour's. Agriculture relies ultimately on the performance of the standard rites, although this in itself is no guarantee of a full harvest, as successful communication with the gods is not certain. A reflection of this etiology is found perhaps in the fact that the irrigation association does not impose sanctions for failure to observe the ceremonies on individual plots, as it is felt that the omission will provoke its own retribution.

Nor is this view of the ascription of responsibility to the gods simply a theological doctrine, remote from the everyday ideas of peasant farmers. Divine involvement in agriculture is recognised in popular thought, as the following case should demonstrate:

In 1969, the level of water reaching Subak Langkik began to drop seriously (according to all the informants who were agreed on the outline of the story given here). This was attributed to the permission granted by the government irrigation officer, sedahang agung, to three new subak upstream to tap the existing supply. Shortly after the third, and largest, of these began to irrigate, the medium of the Pura Duaa Bingin went into trance and announced that Ratu Cede (the male Barong Landung mentioned above) wished to go with his consort to visit his 'brother', the deity of the watershed temple near the river source at Apuh. This was taken as a sign by the villagers that the god was intervening publicly in the disagreement over water. So, when the day came, the two Barong were accompanied in procession by over 400 people up to the mountains where they stayed in the temple overnight. Immediately afterwards the water-level is said to have returned to normal, or even increased. Over a year later, people still insisted on taking me to the main feeder canal to demonstrate the improvement.

This suggests that the role of the gods in agriculture is not merely as vague forces who must be supplicated in the hope that they will respond with routine benefits, but as important agents who may step in of their own accord unanticipated, so that their intervention may be part of an immediate framework of action.
In contrast, ethnographic enquiry suggests a different interpretation to that offered in village religious belief. In reality, there are a number of common threats to the crop within the traditional technological limits of wet rice cultivation, not all of which stem from the uncontrollable forces of nature. Perhaps the most serious, but fortunately rare, hazard is rain during the short flowering period, which may prevent fertilisation of the flowers. More frequent is a reduction in yield due to rain (and sometimes wind) just before harvest, which flattens the top-heavy stalks and may result in premature germination and difficulties in reaping. The other main problem is the depredation of pests, merana (principally mice, birds and insects), but this is rarely severe, as the widespread practice of synchronising crop cultivation reduces the damage per unit area. As was noted in Tengahpadang, there are no immediate remedial rites in the event of these dangers materialising. The great ceremony to ward off pests, nangkur merana, is held for the region as a whole on the coast at Lebih in December (on Tilam Karam, between the sixth and seventh Hindu-Balinese months) when the fields are empty anyhow.  

As a few villagers were willing to admit privately, the factors most widely responsible for reducing productivity are of two principal types: the sheer incompetence of, and social pressures on, individuals; and the inefficiency, for various reasons, of the subak association. Farmers differ in their skill and diligence. They are also under moral obligation to engage in various forms of labour exchange, ranging from co-membership of special agricultural voluntary associations, through mutual help, to straight mobilisation of clients. To evade this may well be economical, but carries with it high social costs (Barth 1963: 8-9). While these constraints may help to account for individual variation, they are not directly relevant to the working of the irrigation association as a corporate group.

Although Tengahpadang lies some way up the sloping plateau of South Bali and has an adequate supply of water in theory, as it is not too far from the river source, the pattern of co-ordinated but fluctuating demand results in shortage (Adatrechtsbundes XV: 50). Despite an elaborate penal code (awig-awigsubak) reinforced by sizeable fines, the deficiency leads to, and is exacerbated by, universal theft (see Liefrinck 1969: 52). This is normally achieved by blocking off all one's neighbours' supplies at the dividing-blocks for some distance back up the irrigation channel. It also creates the possibility of conflict in periods of acute shortage. The scale of pilfering is such that application of the rules is more or less impossible. The constantly changing forms of guard duty which attempt to cope with the problem are ineffective in dealing with the innumerable daily infractions, and may indeed fuel the disagreements (see below). As a consequence, a significant drain on labour stems

10. Repairs on minor damage to an irrigation channel in Subak Langkih
Reconstruction in progress on the weir at Mundak Bolo from the demands of surveillance and from the continual erection and destruction of diversions with serious implications for those with rice land at the lower extremities of the channels. The simple administrative problems of organising the equitable distribution of water, and ensuring obedience to the rules, is almost insoluble in practice. Nature is, in many ways, a far more remote threat to the Balinese peasant than are his agricultural neighbours; but it is the former which is magnified in ritual, while the disruption caused by the latter receives no cultural expression.

A graver danger still is posed by the lack of capital investment in irrigation works. For example, Tengahpadang and the mountainous regions behind receive heavy and uneven rainfall, with the perennial risk of sudden inundation. This may result either in the silting-up of the ingenious, but simple, system of sluices and overflow-spills and send sand or mud spewing through the irrigation network, or in sections of the channels being washed away entirely. The frequent rupture or blockage of the ducts can deluge certain fields and damage terracing and, at the same time, leave others dry. On several occasions, whole parts of Subak Langkih were waterless for days on end during critical periods of the cycle. In one têmpêk (Langkih) alone, in the first sixteen days of December 1971 (admittedly a worse time than most as it is at the beginning of the rainy season), there were four incidents of broken canals and one landslide which destroyed an entire length of conduit. A few years earlier, after a particularly disastrous series of collapses, concrete dividing-blocks and banks were introduced at the worst points, but almost all the system still consists of simple mud and stone channels, which breach easily and require constant, and often difficult, repair. While Balinese indigenous technology is remarkably sophisticated (Adatrechtbundele XV: 29-37; Liefbrinck 1927: 70 & 76-91, or 1969: 47-57), actual investment seems to vary greatly between subak and to be far lower than the potential. To understand some of the reasons, it is necessary to turn to the structure of the irrigation association itself.

Langkih, as all the other subak in the area, is run according to a strictly democratic set of rules, backed up by the ideal of the equality of all members, regardless of status or wealth. In general, for example, Balinese ritual may be conducted at a number of different levels categorised into nîsta, low, madhya, medium, and utama as the highest. The choice for individuals in most situations varies with considerations of prestige and available resources. It is of interest then that I was informed that all agricultural rites conducted in the fields should properly be nîsta; although this is partly to be explained by the fact that a larger ceremony would be pure inconspicuous consumption, as they are performed alone. Equally, contributions to association temple ceremonies, labour obligations and voting rights are the same for all members, independent of differences in land or water holdings.
The structure and ideology of the *subak* disguise, however, under a jural and normative cloak, the profound inequalities, divergences in economic interests and internal tensions which stem from real discrepancies in the command of resources. The formal and legal equality of association members serves, in fact, to suppress and deny the differences in wealth and power which exist. In contrast to the local residential groups, the *barka*, which have somewhat similar constitutions, but where a number of different factors encourages the development of patron-client ties (Hobart 1975), such informal groupings do not seem to emerge here. Instead, for the most part villagers are atomised and set against one another by their competing concerns in water. In certain situations, though, decision-making is influenced by sub-sections of the *subak* with rival demands, and more importantly, by informal groupings with allied economic interests. For the major decisions, not uncommonly, centre on the problem of improving the irrigation system which requires in turn capital investment. This tends to split the group in terms of wealth, despite the rules that contributions are scaled according to the amount of water contracted, the payments weigh far more heavily on the poor subsistence farmers who have few, if any, spare funds. In this case, as they are generally in the majority (see n.3 above), the usual pattern is for the plans for amelioration to remain shelved until a sufficient crisis impels the members to minimal action. Underneath the seeming equality of the irrigations association (Birkelbach 1973: 165-9), there are profound differences.

These problems can perhaps be seen more clearly by a consideration of the example below:

Tempek Langkih possesses six branch canals which feed its various sub-sections. One of these, Munduk Bolo, obtains water from the main stream by means of a weir which raises the level by some three metres above its natural course, and consists of simple tree trunks supporting a bed of volcanic sand. The construction is unstable but cheap, and it tends to get carried away in heavy rainstorms. On the occasion which I witnessed, in early December 1971, the weir broke and flooded a number of fields lower down. This had the effect of cutting off Munduk Bolo’s supply of water just at the time that the fields required soaking, in order to soften them for hoeing, so that work was interrupted. After a brief consultation of the *tempek* council officials, it was decided that the responsibility lay with Munduk Bolo, which consistently refused to install a more permanent structure for reasons of cost. Intense discussion ensued during which the three reasonably wealthy members (with two *bit temah* each) tried to persuade the sixteen others (with one *bit*, or fractions) to raise the money for a concrete dam, while they negotiated simultaneously for support from the *tempek*. The plans came to nothing and more time passed before the poor members eventually scraped together their contributions (in more than one case, this was lent by the rich to speed matters up) to purchase the cheapest, but least durable, tree trunks available. Five days after the initial breach, the weir was working again, but it took several days before the limited supply could soak the fields sufficiently to enable normal work to proceed, now seriously off-schedule. Within ten days the canal broke higher up, and a few months later the weir collapsed once more.

On this occasion, a certain degree of tension was evident between the richer farmers who had the ready cash to invest in a solid irrigation dam and stood to benefit proportionately more if it were built, and the poor who in some instances had not even spare padi to sell from the previous harvest.

This opposition came out in another context, in the arguments over changes in the system of guard duty, *tali*'. For three seasons, this had been performed by the *tempek* as a whole, divided into teams, *regu*, who took turns to patrol the ricefields. Unsurprisingly, this led to abuses, when people tended to fine their personal enemies but ignore the dubious activities of their friends. In addition, the big landowners seemed to be penalised far more often than the poor. Following a violent altercation which blew up unexpectedly one evening in June 1972, the *tempek* meeting agreed to appoint officials specially for the task. It is interesting that each of these happened to come from a family with extensive ricelands.

Although there are numerous gradations in the size of peasant holdings in Subak Langkih so that there is no simple dichotomy in local thought, evidence points to a trend towards conflict between relatively small- and large-scale farmers, in the pattern of serious quarrels which break out in the ricefields. In all I have records of five recent incidents which led to violence or a complete breach of social relations. This is hardly an adequate sample for substantial generalisation, but it may still be significant that, of these, four were between men who owned two and five *bit temah* (or from 0.57 to 1.43 hectares of irrigated riceland) on the one hand, and those with one *temah* or even less (between 0.11 and 0.37 hectares of land) on the other. The remaining disagreement was between two notoriously cantankerous neighbours both with small plots. It would appear that the need to purchase new or long-dormant equipment was a factor in the disputes which followed the lines of economic difference, which is arguably a reflection of underlying tension within the association.

So it seems that there is a significant discrepancy between the view of agricultural production codified in ritual and that which emerges from an analysis of economic institutions and relationships in practice. The series of rice ceremonies appears, in some ways, to provide a representation of an ideal cycle of cultivation, in which an instrumental role is ascribed to the
participation of certain deities. This suggests one possible interpretation of the common use of calendars which reflect a pre-ordained ritual time-scale, rather than the actual maturation of the crop. One of the effects is to stress the separation of the changeable seasons of the natural world, where agricultural success depends on a range of more or less controllable factors, from the perfect order embodied in the calendars, where the idealised re-creation of farming is placed securely and unequivocally under the authority of supernatural forces. This apart, belief and ritual accentuate human dependence on the appropriate deities for fertility and in avoiding the uncertainties of nature. In fact, however, nature is only one among many hazards and farther more proximate are the difficulties caused individually by members of the irrigation association and by the shortcomings of more proximate justifications caused by individual resource limitations and by the weakness of the administrative and constitutional weaknes ses of the irrigation association itself. Within this, there appear to be conflicts which derive in part from the disparity between the pattern of land-ownership and public influence, or between the reality of divergent economic interests on the one hand, and the ideology of equality on the other. To the extent that ritual provides an alternative representation and diverts thought away from the inherent structural problems of democratically constitut ed groups, it may be said to support the existing social system and preserve egalitarianism by denying its defects.

The culturally elaborated message of ritual attributes responsibility for agricultural prosperity to the gods and, in so doing, provides a convenient collective interpretation of difficulties. Thus, it can be seen as a traditional mode of explanation (Parkin 1975: 137-9) of the fertility of the rice crop, but in recent years other views are becoming apparent with the increasing public discussion about technological innovations. The former remains, however, a particularly attractive alternative to the potentially disruptive examination of the administrative and constitutional weaknesses of the irrigation association itself. Within this, there appear to be conflicts which derive in part from the disparity between the pattern of land-ownership and public influence, or between the reality of divergent economic interests on the one hand, and the ideology of equality on the other. To the extent that ritual provides an alternative representation and diverts thought away from the inherent structural problems of democratically constituted groups, it may be said to support the existing social system and preserve egalitarianism by denying its defects.

As a final note, there is an interesting contrast between the argument outlined earlier in this chapter in 'The Path of the Soul' and in the present contribution. In different ways, they each suggest that symbolic forms and ideology may produce incomplete or inaccurate representations of the state, and implications, of social relationships, and hence obscure certain types of underlying process, in what has variously been termed 'mystification' (Cohen 1969: 220-21; 1974: 31-32), 'misrepresentation' (Bloch 1975: 204ff.), or the creation of a 'culturally alternative explanatory mode' (Parkin 1975: 137). In the first of these two papers, nature is used to justify the inequality between Balinese descent groups by representing the cultural in natural terms; in the latter, nature is used to reaffirm equality within a group by portraying the dangers to it as natural (and their resolution as supernatural), rather than cultural. In the discussion of the caste system, cosmological conceptions help to support and legitimate ideas of hierarchy; in the irrigation association, ritual symbols appear to support and protect the values of corporate solidarity. The notion of 'mystification' has generally been applied to the study of systems of inequality. If nothing else, I hope to have indicated here that it may be just as applicable to the opposite.

NOTES

1. I would like to express my thanks to Dr Maurice Bloch, M.R. Kaplan, Professor Adrian Mayer and Dr David Parkin for making extremely valuable comments on the original version of this paper. My gratitude is also due to Dr C. Hooykaas for being so kind as to assist me not only in my attempts to decipher some of the ritual formulae mentioned here, but also in making available references to certain of the plants and to transcriptions of the different editions of the Taru Pramana. The system of pronunciation of Balinese words is given in 'The Path of the Soul' (n.3) also in this volume.

2. The exceptions which spring to mind include Leach 1964, and perhaps also Fox 1974, while sensory associations feature in a somewhat different fashion in Levi-Strauss 1966: 12-22.

3. These include: Adatrechtbundels XV: Nos.8, 10, 11, & 27; XXII: Nos.42-45; XXXVIII: No.72; Birkebach 1973; Geertz 1967 & 1972a; Grader 1960; Liefrinck 1927, partly translated in 1969; Wirz 1927.

4. The official records for June 1971, of the levies and membership for the five tamplek of Subak Langkhi indicate that, in each, the proportion of peasant farmers with one bit tanah (the modal figure) or less is roughly three-quarters, or even more. The actual percentages (from upstream to down) are:

<table>
<thead>
<tr>
<th>Village</th>
<th>Tamplek</th>
<th>%</th>
</tr>
</thead>
<tbody>
<tr>
<td>Telun Ayah</td>
<td>86.9%</td>
<td></td>
</tr>
<tr>
<td>Uma Dalem</td>
<td>73.9%</td>
<td></td>
</tr>
<tr>
<td>Langkhi</td>
<td>74.1%</td>
<td></td>
</tr>
<tr>
<td>Keraman</td>
<td>86.9%</td>
<td></td>
</tr>
<tr>
<td>Sukabayu</td>
<td>70.2%</td>
<td></td>
</tr>
</tbody>
</table>

The range can be accounted for partly by differences in the wealth of the members of the various wards in the settlement. Although there is no official connexion between irrigation and residence (Geertz 1959: 995-61), there is a fairly clear informal association as the tamplek in this area tend to be dominated numerically by a single banjar which also provides a convenient site for holding its meetings.

5. There appear to be more or less systematised alternatives
for representing or expressing time in Bali, among which
the calendars mentioned are important in defining the ritual
time-table, and the time-scale. Whether or not their for-
mal qualities can usefully be described as cyclical, or even
'particulate' (see the discussion in Geertz 1966b: esp. 81,
n.31) does not necessarily imply that the Balinese are in-
capable of also recognising that time may be seen as sequen-
tial, or non-repetitive (Leach 1961: 125). The views of
the villages were summed up succinctly by the priest of the
local Pura Dalem. He pointed out that, in his official
capacity, he used the above two calendars to estimate ritual
dates; whereas to the majority of people, as they were far-
mers, the cycle of seasons was seen as the most immediately
relevant. For other matters, there was a chronology based
on a series of well-remembered events, including wars, earth-
quakes, and volcanic eruptions, and more recently the offi-
cial (Gregorian) calendar. An idea of the irreversibility of
time would appear to be implied in the local version of
the Hindu theory of karma(pala) (see 'The Path of the Soul'),
or in proverbs or popular sayings, such as: 'words spoken
can never be replaced in the mouth!'

6. In addition, the priest had an unfortunately largely ille-
gible manual, the provenance of which he did not know. It
appeared that, for the limited occasions of its use (see
below), it was gradually being replaced by a printed com-
pendium, produced by the Hindu movement in Bali, the Parisada
Hindu Dharm (Geertz 1972b: 77-8).

7. These are nyungswung and ngasaaba in Table 2.

8. For the background to this, see Hobart 1975: 90-91, where
he is referred to as Candidate N.

9. There are several versions, in which the number of listed
plants varies. In one, translated by Weck (1938: 250-81)
there are 168.

10. They seem to be mainly common woodless species, although
regrettably I did not have the equipment in the field to
permit a detailed botanical examination or classification.

11. Most of the translations are to be found in the invaluable
dictionary by van der Tuuk (1897-1912). In addition, he
gives other homonyms for some of the names, which are in no
way relevant here. Van der Tuuk, however, is not compre-
hensive on this subject and other terms were given by local
informants, or are to be found in van Eck 1876.

12. Within the actual periodicity of performance, the rites may
portray an order in which there is juxtaposition or repeti-
tion of successive phases of agriculture, in a manner re-
miniscent in some ways of Becker's recent argument (1976)
about the qualities of plot and time in the Javanese
shadow-theatre.

13. Members may meet fleetingly, or at least pass through the
same village temples (in particular, the Pura Badi Agung
and Pura Maeedit; see Goris 1960b and 1960a) during the
preparation or collection of holy water, tirtha, made by
the priests before some, but not all, of the individual
rites.

14. According to Geertz (1966b: 46), this is the product of the
six- and seven-day weeks; but C. Hooykaas (personal com-
munication) has argued in response that this is, in fact, the
common thirty-five day cycle (tumpok; Goris 1960a: 117)
with an extra seven-day week added.

15. The soil is thought to be unsuitable for ploughing in this
part of the island.

16. Some interesting features of the rice cycle in the region of
Tengahmandang emerged from a helpful discussion with Dr
Ronald Ng. First, the vegetative period seems to be ex-
tended by the practice of regular drying of the fields.
Then the time from the emergence of the panicle to flower-
ing, and till harvest appear to be foreshortened in the
same way. Harvesting itself is advanced as the traditional
varieties of padi are reaped and carried still on the stalk
to be dried at leisure in the compound.

17. There is little reason to think that the problem of timing
can be explained by recourse to a theory of historical
diffusion or by reference to possible changes in the varie-
ties of padi. The two calendars between them offer great
flexibility and the particular use varies widely from area
to area. Whereas in Subak Langkih the rites are held for
the most part at fifteen day intervals, in the lowland
region round Sukawati in South Gianyar, this is less fre-
quent. In one instance, the ceremonial cycle is scheduled
strictly every 35 days, on either Sukra-matIs or Buda-
klI(won), by combination of the seven- and five-day weeks
to produce five ceremonies in all between transplanting and
harvest.

18. Geertz (1967: 233-5) reports a different type of system
involving staggered cycles between tempek in Klungkung and
referred to just as masa (but cf. Korn 1952: 72 & 609).

19. The marga used by the local priest, which he stated to be
in Sanscrit (cf. C. Hooykaas 1973b: 14-5) turned out unfor-
tunately to be largely unintelligible. In the one mentioned
here, part was in Balinese, and so was translatable.

20. For brief notes on this rite, see Swellengrebel 1960: 38.

21. The type of problems differs with local topography.
Further complexities which are not discussed here, emerge
in the past, as there is the question of exactly how in-
vestment in the irrigation system came about. This seems
to be more by princely intervention at times (Adatrechtbundes
